

Portfolio CSS Changes Guide (Beginner-Friendly)

This guide explains every layout and styling update made to your portfolio so you can learn the resp

What Was Fixed

1. Desktop spacing felt uneven with too much open space on the right side.
2. Header and body layout looked uneven on phones.
3. There was no entry transition when opening the website.

1) Centering the layout on large screens

Problem

Your sections were anchored to the left using `justify-content: flex-start`, and some cards had manual

Fix

- Added a centered container for all page content:
 - `main { max-width: 1200px; margin: 0 auto; }`
- Updated section rows (`.main-first`, `.main-second`, `.main-third`) to:
 - `justify-content: center`
 - `flex-wrap: wrap`
 - a cleaner, consistent gap
- Removed manual left-push margins on main cards.

Why it works

`max-width` prevents super-wide stretching, and `margin: 0 auto` centers the whole content block. Center

2) Making the header and body responsive for phones

Header improvements

Problem

- Header spacing relied on hard-coded margins.
- Buttons used duplicate IDs (`id="Resume"` repeated), which is invalid HTML.

Fix

- Replaced duplicate button IDs with a reusable class: `.header-button`.
- Renamed buttons to distinct labels:
 - Resume
 - Projects
 - Contact
- Converted header groups into flexible rows that wrap naturally.
- Added tablet and mobile rules so title, buttons, and icons align evenly.

Why it works

Classes are reusable and valid for multiple elements. Flex wrapping and mobile breakpoints let compo

Body/card improvements

Problem

- Several cards used fixed heights and strict minimum widths.
- On smaller devices this can create cramped content, uneven spacing, and overflow.

Fix

- Standardized card sizing with responsive flex values.
- On mobile (max-width: 768px), switched major cards to height: auto so content defines the height.
- Relaxed strict min-width behavior at smaller breakpoints.
- Adjusted text/image sizing and spacing for smaller screens.
- Improved stacking for intro section and list sections.

Why it works

Responsive layouts should prioritize fluid sizing. height: auto on mobile avoids clipping, and small

3) Adding a simple fade-in on page load

Problem

The page appeared instantly without transition.

Fix

- Added a keyframe animation to the body:
 - starts at opacity: 0
 - ends at opacity: 1
 - duration: 0.7s
- Added reduced-motion support:
 - @media (prefers-reduced-motion: reduce) disables animation and transitions.

Why it works

Fade-in adds a gentle first impression. Reduced-motion support keeps the experience accessible for u

File-by-file changes

index.html

- Updated header buttons from duplicate IDs to class-based buttons.
- Changed labels to Resume, Projects, and Contact.

Scripts/CSS/header.css

- Added page fade-in animation and keyframes.
- Centered header container with max width.
- Refactored button styling from #Resume to .header-button.
- Improved responsive behavior for tablet and mobile.
- Added reduced-motion fallback.

Scripts/CSS/main.css

- Added centered main container with max width.
- Centered row layouts and standardized spacing.

- Removed manual left offsets from bordered cards.
- Improved card width behavior for large screens.
- Added responsive breakpoints for tablet/phone.
- Switched card heights to auto on mobile.

Quick CSS Concepts You Just Used

- max-width + margin: 0 auto = centered content block on large screens.
- display: flex + flex-wrap: wrap = responsive row that can stack naturally.
- flex: 1 1 320px = grow and shrink, with a preferred base width.
- Media queries (@media) = apply rules only for certain viewport widths.
- height: auto = let content control the box height.
- @keyframes + animation = create entry transitions.
- prefers-reduced-motion = accessibility-friendly motion handling.

How to tweak this later (safe edits)

If you want to customize the look further:

1. Wider/narrower desktop content:
 - edit main { max-width: 1200px; } in Scripts/CSS/main.css.
2. More/less spacing between cards:
 - edit gap in .main-first, .main-second, .main-third.
3. Faster/slower fade-in:
 - edit animation: pageFadeIn 0.7s ... in Scripts/CSS/header.css.
4. Earlier/later phone layout switch:
 - adjust values in media queries (900px, 768px, 480px).

Final outcome

You now have:

- A centered, balanced desktop layout.
- A cleaner and more even phone/tablet layout.
- A simple and accessible page-entry fade-in.

These are core responsive CSS patterns used in real-world production websites.
